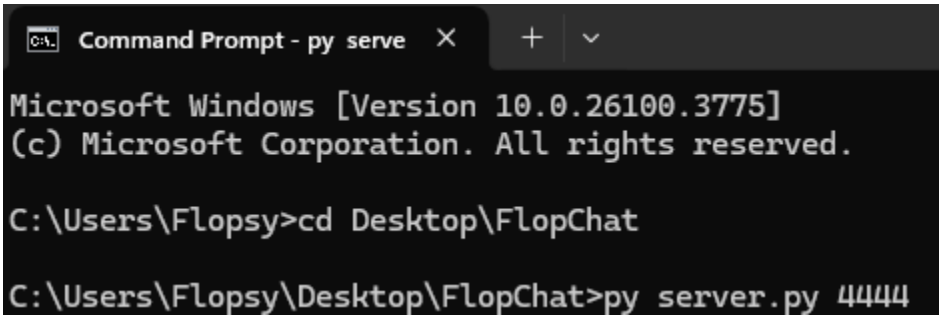
Sean Zhang “FlopChat” Report

Instructions

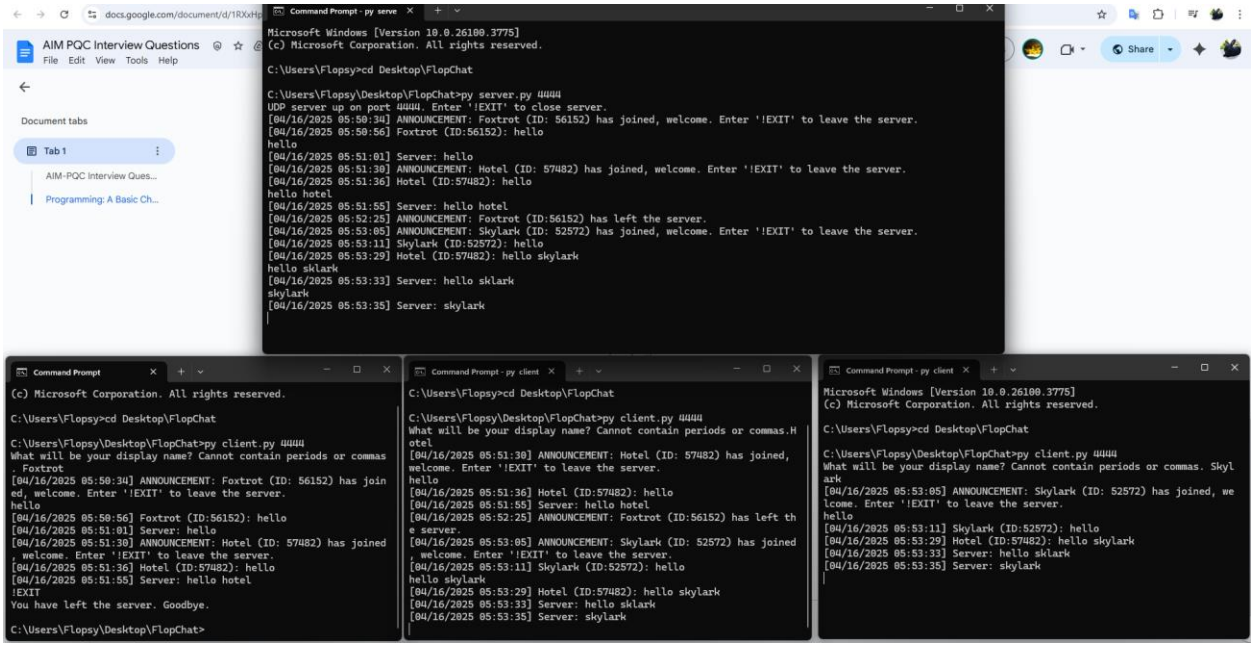
The client.py and server.py files are run with command line interfaces.

You will need Python installed on your machine (I was using version 3.13).

Below is an example of how to run the server file (client.py for client file) that also takes an argument for the server/client port number. This particular example path is for when the directory is on the Windows desktop.



Below is how to have multiple clients connect to the server: having multiple instances of a command line interface run client.py



Operation and Features

-Multiple clients with each client receiving server broadcasts of messages that other clients and the server sent.

-The chat is implemented using UDP. The server used one socket to communicate with all clients

-Timestamps for each message broadcasted

-Clients input their own display name which is shown in their messages

-Clients also have their unique Chat ID using their UDP port. (Each client upon creation binds to available port, meaning no concurrent users will have same ID)

-All broadcasts are logged in the directory's ChatHistory.txt file
